Abstract

Let $(1)Rh = f$, $0 \leq x \leq L$, $Rh = \int_0^L R(x, y)h(y) dy$, where the kernel $R(x, y)$ satisfies the equation $QR = P\delta(x - y)$. Here Q and P are formal differential operators of order n and $m < n$, respectively, n and m are nonnegative even integers, $n > 0$, $m \geq 0$, $Qu := q_n(x)u^{(n)} + \sum_{j=0}^{n-1} q_j(x)u^{(j)}$, $Ph := h^{(m)} + \sum_{j=0}^{m-1} p_j(x)h^{(j)}$, $q_n(x) \geq c > 0$, the coefficients $q_j(x)$ and $p_j(x)$ are smooth functions defined on $\mathbb{R}$, $\delta(x)$ is the delta-function, $f \in H^\alpha(0, L)$, $\alpha := \frac{n-m}{2}$, H^α is the Sobolev space.

An algorithm for finding analytically the unique solution $h \in \dot{H}^{-\alpha}(0, L)$ to (1) of minimal order of singularity is given. Here $\dot{H}^{-\alpha}(0, L)$ is the dual space to $H^\alpha(0, L)$ with respect to the inner product of $L^2(0, L)$.

Under suitable assumptions it is proved that $R : \dot{H}^{-\alpha}(0, L) \rightarrow H^\alpha(0, L)$ is an isomorphism.

Equation (1) is the basic equation of random processes estimation theory. Some of the results are generalized to the case of multidimensional equation (1), in which case this is the basic equation of random fields estimation theory.

1 Introduction

In monograph [1] (see also [3]) estimation theory for random fields and processes is constructed. The estimation problem for a random process is as follows. Let $u(x) = s(x) + n(x)$ be a random process observed on the interval $(0, L)$, $s(x)$ is a useful signal and $n(x)$ is noise. Without loss of generality we assume that $\overline{s(x)} = \overline{n(x)} = 0$, where the overbar stands for the mean value, $u^*(x)u(y) := R(x, y)$, $R(x, y) = \overline{R(y, x)}$, $u^*(x)s(y) := f(x, y)$, and the star here stands for complex conjugate. The covariance functions $R(x, y)$

Key words: integral equations, estimation theory

Math subject classification: 45A05, 45H05, 93E10, 93E11, 34A30

and $f(x, y)$ are assumed known. One wants to estimate $s(x)$ optimally in the sense of minimum of the variance of the estimation error. More precisely, one seeks a linear estimate

$$Tu = \int_0^L h(x, y)u(y) dy, \quad (1.1)$$

such that

$$\overline{|(Tu)(x) - s(x)|^2} = \min. \quad (1.2)$$

This is a filtering problem. Similarly one can formulate the problem of optimal estimation of $(As)(x)$, where A is a known operator acting on $s(x)$. If $A = I$, where I is the identity operator, then one has the filtering problem, if A is the differentiation operator, then one has the problem of optimal estimation of the derivative of s , if $As = s(x + x_0)$, then one has an extrapolation problem, etc. The kernel $h(x, y)$ is, in general, a distribution. As in [1], one derives a necessary condition for h to satisfy (1.2):

$$\int_0^L R(x, y)h(y, z) dy = f(x, z), \quad 0 \leq x, z \leq L. \quad (1.3)$$

Since z enters as a parameter in (1.3), the basic equation of estimation theory is:

$$Rh := \int_0^L R(x, y)h(y) dy = f(x), \quad 0 \leq x \leq L. \quad (1.4)$$

The operator in $L^2(0, L)$ defined by (1.4) is symmetric. In [1] it is assumed that the kernel

$$R(x, y) = \int_{-\infty}^{\infty} \frac{P(\lambda)}{Q(\lambda)} \Phi(x, y, \lambda) d\rho(\lambda), \quad (1.5)$$

where $P(\lambda)$ and $Q(\lambda)$ are positive polynomials, $\Phi(x, y, \lambda)$ and $d\rho(\lambda)$ are spectral kernel and, respectively, spectral measure of a selfadjoint ordinary differential operator ℓ in $L^2(\mathbb{R})$, $\deg Q(\lambda) = q$, $\deg P(\lambda) = p < n$, $p \geq 0$, $\text{ord } \ell := \sigma > 0$. Actually in [1] the multidimensional case, when $x, y \in \mathbb{R}^r$, $r > 1$, and ℓ is a selfadjoint elliptic operator in $L^2(\mathbb{R}^r)$ is also considered.

It is proved in [1] that the operator $R : \dot{H}^{-\alpha}(0, L) \rightarrow H^{\alpha}(0, L)$, $\alpha := \frac{n-m}{2}\sigma$ is an isomorphism. By $H^{\alpha}(0, L)$ the Sobolev space $W^{\alpha, 2}(0, L)$ is denoted, and $\dot{H}^{-\alpha}(0, L)$ is the dual space to $H^{\alpha}(0, L)$ with respect to $L^2(0, L) := H^0(0, L)$ inner product. Namely, $\dot{H}^{-\alpha}(0, L)$ is the space of distributions h which are linear bounded functionals on $H^{\alpha}(0, L)$. The norm of $h \in \dot{H}^{-\alpha}(0, L)$ is given by the formula

$$\|h\|_{\dot{H}^{-\alpha}(0, L)} = \sup_{g \in H^{\alpha}(0, L)} \frac{|(h, g)|}{\|g\|_{H^{\alpha}(0, L)}}, \quad (1.6)$$

where (h, g) is the $L^2(0, L)$ inner product if h and g belong to $L^2(0, L)$.

One can also define $\dot{H}^{-\alpha}(0, L)$ as the subset of the elements of $H^{-\alpha}(\mathbb{R})$ with support in $[0, L]$.

In this paper we generalize the class of kernels $R(x, y)$ defined in (1.5): we do not use the spectral theory, do not assume ℓ to be selfadjoint, and do not assume that the operators Q and P commute.

We assume that

$$QR = P\delta(x - y), \quad (1.7)$$

where Q and P are formal differential operators of orders n and m respectively, $n > m \geq 0$, n and m are even integers, $\delta(x)$ is the delta-function,

$$Qu := \sum_{j=0}^n q_j(x)u^{(j)}, \quad q_n(x) \geq c > 0, \quad Ph := h^{(m)} + \sum_{j=0}^{m-1} p_j(x)h^{(j)}, \quad (1.8)$$

where q_j and p_j are smooth functions defined on $\mathbb{R}$. We also assume that the equation $Qu = 0$ has $\frac{n}{2}$ linearly independent solutions $u_j^- \in L^2(-\infty, 0)$ and $\frac{n}{2}$ linearly independent solutions $u_j^+ \in L^2(0, \infty)$. In particular, this implies that if $Qh = 0$, $h \in H^\alpha(\mathbb{R})$, $\alpha > 0$, then $h = 0$, and the same conclusion holds for $h \in H^\beta(\mathbb{R})$ for any fixed real number β , including negative β , because any solution to the equation $Qh = 0$ is smooth: it is a linear combination of n linearly independent solution to this equation, each of which is smooth and none belongs to $L^2(\mathbb{R})$.

Let us assume that $R(x, y)$ is a selfadjoint kernel such that

$$c_1 \|\varphi\|_-^2 \leq (R\varphi, \varphi) \leq c_2 \|\varphi\|_-^2, \quad c_1 = \text{const} > 0, \quad \forall \varphi \in C_0^\infty(\mathbb{R}), \quad (1.9)$$

where $(\cdot, \cdot)$ is the $L^2(\mathbb{R})$ inner product, $\|\varphi\|_- := \|\varphi\|_{H^{-\alpha}(\mathbb{R})} := \|\varphi\|_{-\alpha}$, $\alpha := \frac{n-m}{2}$, $\|\varphi\|_\beta := \|\varphi\|_{H^\beta(\mathbb{R})}$, and we use below the notation $\|\varphi\|_+ := \|\varphi\|_{H^\alpha(0, L)} := \|\varphi\|_{H^+}$. The spaces $H^\alpha(0, L)$ and $\dot{H}^{-\alpha}(0, L)$ are dual of each other with respect to the $L^2(0, L)$ inner product, as was mentioned above. If $\varphi \in \dot{H}^{-\alpha}(0, L)$, then $\varphi \in H^{-\alpha}(\mathbb{R})$, and the inequality (1.9) holds for such φ . By this reason we also use (for example, in the proof of Theorem 1.1 in Section 2) the notation H^- for the space $\dot{H}^{-\alpha}(0, L)$.

Assumption (1.9) holds, for example, if the following inequalities (1.10) and (1.11) hold:

$$c_3 \|\varphi\|_{-\alpha+n} \leq \|Q^*\varphi\|_{-\alpha} \leq c_4 \|\varphi\|_{-\alpha+n}, \quad c_3, c_4 = \text{const} > 0, \quad \forall \varphi \in C_0^\infty(\mathbb{R}), \quad (1.10)$$

$$c_5 \|\varphi\|_{\frac{n+m}{2}}^2 \leq (PQ^*\varphi, \varphi) \leq c_6 \|\varphi\|_{\frac{n+m}{2}}^2, \quad \forall \varphi \in C_0^\infty(\mathbb{R}), \quad (1.11)$$

where Q^* is a formally adjoint to Q differential expression, and c_5 and c_6 are positive constants independent of $\varphi \in C_0^\infty(\mathbb{R})$. The right inequality (1.11) is obvious because $\text{ord } PQ^* = n + m$, and the right inequality (1.10) is obvious because $\text{ord } Q^* = n$.

Let us formulate basic results of this paper.

Theorem 1.1. *If (1.9) holds, then the operator R , defined in (1.5), is an isomorphism of $\dot{H}^{-\alpha}(0, L)$ onto $H^\alpha(0, L)$, $\alpha = \frac{n-m}{2}$.*

Theorem 1.2. *If (1.7), (1.10) and (1.11) hold, then (1.9) holds and $R : \dot{H}^{-\alpha}(0, L) \rightarrow H^\alpha(0, L)$ is an isomorphism.*

Theorem 1.3. *If (1.7), (1.10) and (1.11) hold, and $f \in H^n(0, L)$, then the solution to (1.4) in $\dot{H}^{-\alpha}(0, L)$ does exist, is unique, and can be calculated analytically by the following formula:*

$$h = \int_0^x G(x, y) Qf dy + \sum_{j=0}^{n-\alpha-1} [a_j^- (-1)^j G_y^{(j)}(x, 0) + a_j^+ (-1)^j G_y^{(j)}(x, L)], \quad (1.12)$$

where $a_j^\pm$ are some constants and $G(x, y)$ is the unique solution to the problem

$$PG = \delta(x - y), \quad G(x, y) = 0 \text{ for } x < y. \quad (1.13)$$

The constants $a_j^\pm$ are uniquely determined from the condition $h(x) = 0$ for $x > L$.

Remark 1.4. *The solution $h \in \dot{H}^{-\alpha}(0, L)$ is the solution to equation (1.4) of minimal order of singularity (see [1]).*

Remark 1.5. *If $P = 1$ in (1.7) then the solution h to (1.4) of minimal order of singularity, $h \in \dot{H}^{-\frac{n}{2}}(0, L)$, can be calculated by the formula $h = QF$, where F is given by (2.9) (see below) and u_+ and u_- are the unique solutions of the problems $Qu_+ = 0$ if $x > L$, $u_+^{(j)}(L) = f^{(j)}(L)$, $0 \leq j \leq \frac{n}{2} - 1$, $u_+(\infty) = 0$, and $Qu_- = 0$ if $x < 0$, $u_-^{(j)}(0) = f^{(j)}(0)$, $0 \leq j \leq \frac{n}{2} - 1$, $u_-(-\infty) = 0$.*

2 Proofs

Proof of Theorem 1.1. The set $C_0^\infty(0, L)$ is dense in $\dot{H}^{-\alpha}(0, L)$ (in the norm of $H^{-\alpha}(\mathbb{R})$). Using the right inequality (1.9), one gets:

$$\|R\|_{H^- \rightarrow H^+} = \sup_{h \in H^-} \frac{(Rh, h)}{\|h\|_-^2} \leq c_2, \quad (2.1)$$

by the symmetry of R in $L^2(0, L)$ (cf [1, p.40]). This implies $\|R\|_{H^- \rightarrow H^+} \leq c_2$. Using the left inequality (1.9), one gets: $c_1 \|h\|_-^2 \leq \|Rh\|_+ \|h\|_-$, so

$$c_1 \|h\|_- \leq \|Rh\|_+. \quad (2.2)$$

Therefore

$$\|R^{-1}\|_{H^+ \rightarrow H^-} \leq \frac{1}{c_1}. \quad (2.3)$$

Consequently, the range $\text{Ran}(R)$ of R is a closed subspace of H^+ . In fact, $\text{Ran}(R) = H^+$. Indeed, if $\text{Ran}(R) \neq H^+$, then there exists a $g \in H^-$ such that $0 = (R\psi, g) \forall \psi \in H^-$. Taking $\psi = g$ and using the left inequality (1.9) one gets $\|g\|_- = 0$, so $g = 0$. Thus $\text{Ran}(R) = H^+$.

Theorem 1.1 is proved. $\square$

Proof of Theorem 1.2. From (1.7) and (1.8) it follows that the kernel $R(x, y)$ defines a pseudodifferential operator of order $-2\alpha = m - n$. In particular, this implies the right inequality (1.9). In this argument inequalities (1.10) and (1.11) were not used.

Let us prove that (1.10) and (1.11) imply the left inequality (1.9).

One has

$$\|Q^*\varphi\|_{-\alpha} \leq C\|\varphi\|_{n-\alpha}, \quad \forall \varphi \in C_0^\infty(\mathbb{R}), \quad (2.4)$$

because $\text{ord } Q^* = n$. Inequality (1.10) reads:

$$c_3\|\varphi\|_{-\alpha+n} \leq \|Q^*\varphi\|_{-\alpha} \leq c_4\|\varphi\|_{-\alpha+n}, \quad \forall \varphi \in C_0^\infty(\mathbb{R}), \quad (2.5)$$

where c_3 and c_4 are positive constants. If (2.5) holds, then $Q^* : H^{-\alpha+n}(\mathbb{R}) \rightarrow H^{-\alpha}(\mathbb{R})$ is an isomorphism of $H^{-\alpha+n}(\mathbb{R})$ onto $H^{-\alpha}(\mathbb{R})$ provided that $N(Q) := \{w : Qw = 0, w \in H^\alpha(\mathbb{R})\} = \{0\}$. Indeed, if the range of Q^* is not all of $H^{-\alpha}(\mathbb{R})$, then there exists an $w \neq 0$, $w \in H^\alpha(\mathbb{R})$ such that $(Q^*\varphi, w) = 0 \quad \forall \varphi \in C_0^\infty(\mathbb{R})$, so $Qw = 0$. If $Qw = 0$ and $w \in H^\alpha(\mathbb{R})$, then, as was mentioned below formula (1.8), it follows that $w = 0$. This proves that $\text{Ran}(Q^*) = H^{-\alpha}(\mathbb{R})$.

Inequality (1.11) is necessary for the left inequality (1.9) to hold. Indeed, let $\psi = Q^*\varphi$, $\varphi \in C_0^\infty(\mathbb{R})$, then (1.9) implies

$$c\|\varphi\|_{-\alpha+n}^2 \leq c\|Q^*\varphi\|_{-\alpha}^2 \leq (RQ^*\varphi, Q^*\varphi) = (QRQ^*\varphi, \varphi) = (PQ^*\varphi, \varphi), \quad (2.6)$$

where $c > 0$ here (and elsewhere in this paper) stands for various estimation constants. Because $-\alpha + n = \frac{n+m}{2}$, inequality (2.6) is the left inequality (1.11). The right inequality (1.11) is obvious because the order of the operator PQ^* equals to $n + m$.

Let us prove now that inequalities (1.11) and (1.10) are sufficient for the left inequality (1.9) to hold.

Using the right inequality (1.10) and the left inequality (1.11), one gets:

$$c\|\psi\|_{-\alpha}^2 \leq c_5\|\varphi\|_{\frac{n+m}{2}}^2 \leq (PQ^*\varphi, \varphi) = (R\psi, \psi), \quad \psi = Q^*\varphi, \quad \forall \varphi \in C_0^\infty(\mathbb{R}). \quad (2.7)$$

Let us prove that the set $\{\psi\} = \{Q^*\varphi\}_{\varphi \in C_0^\infty(\mathbb{R})}$ is dense in $\dot{H}^{-\alpha}(0, L)$. Assume the contrary. Then there is an $h \in \dot{H}^{-\alpha}(0, L)$, $h \neq 0$, such that $(Q^*\varphi, h) = 0$ for all $\varphi \in C_0^\infty(\mathbb{R})$. Thus, $(\varphi, Qh) = 0$ for all $\varphi \in C_0^\infty(\mathbb{R})$. Therefore $Qh = 0$, and, by the argument given below formula (1.8), it follows that $h = 0$. This contradiction proves that the set $\{Q^*\varphi\}_{\varphi \in C_0^\infty(\mathbb{R})}$ is dense in $\dot{H}^{-\alpha}(0, L)$.

Consequently, (2.7) implies the left inequality (1.9). The right inequality (1.9) is an immediate consequence of the observation we made earlier: (1.7) and (1.8) imply that R is a pseudodifferential operator of order $-2\alpha = -(n + m)$.

Theorem 1.2 is proved. $\square$

Proof of Theorem 1.3. Equations (1.4) and (1.7) imply

$$Ph = g := QF. \quad (2.8)$$

Here

$$F := \begin{cases} u_-, & x < 0, \\ f, & 0 \leq x \leq L, \\ u_+, & x > L, \end{cases} \quad (2.9)$$

where

$$Qu_- = 0, \quad x < 0, \quad (2.10)$$

$$Qu_+ = 0, \quad x > L, \quad (2.11)$$

and u_- and u_+ are chosen so that $F \in H^\alpha(\mathbb{R})$. This choice is equivalent to the conditions:

$$u_-^{(j)}(0) = f^{(j)}(0), \quad 0 \leq j \leq \alpha - 1, \quad (2.12)$$

$$u_+^{(j)}(L) = f^{(j)}(L), \quad 0 \leq j \leq \alpha - 1. \quad (2.13)$$

If $F \in H^\alpha(\mathbb{R})$, then $g := QF \in H^{\alpha-n}(\mathbb{R}) = H^{-\frac{n+m}{2}}(\mathbb{R})$, and, by (2.9), one gets:

$$g = Qf + \sum_{j=0}^{n-\alpha-1} [a_j^- \delta^{(j)}(x) + a_j^+ \delta^{(j)}(x-L)], \quad (2.14)$$

where $a_j^\pm$ are some constants. There are $n - \alpha = \frac{n+m}{2}$ constants a_j^+ and the same number of constants a_j^- .

Let $G(x, y)$ be the fundamental solution of the equation

$$PG = \delta(x - y) \text{ in } \mathbb{R}, \quad (2.15)$$

which vanishes for $x < y$:

$$G(x, y) = 0 \text{ for } x < y. \quad (2.16)$$

Claim. *Such $G(x, y)$ exists and is unique. It solves the following Cauchy problem:*

$$PG = 0, \quad x > y, \quad G_x^{(j)}(x, y) \Big|_{x=y+0} = \delta_{j, m-1}, \quad 0 \leq j \leq m-1, \quad (2.17)$$

satisfies condition (2.16), and can be written as

$$G(x, y) = \sum_{j=1}^m c_j(y) \varphi_j(x), \quad x > y, \quad (2.18)$$

where $\varphi_j(x)$, $1 \leq j \leq m$, is a linearly independent system of solutions to the equation:

$$P\varphi = 0. \quad (2.19)$$

Proof of the claim. The coefficients $c_j(y)$ are defined by conditions (2.17):

$$\sum_{j=1}^m c_j(y) \varphi_j^{(k)}(y) = \delta_{k,m-1}, \quad 0 \leq k \leq m-1. \quad (2.20)$$

The determinant of linear system (2.20) is the Wronskian $W(\varphi_1, \dots, \varphi_m) \neq 0$, so that $c_j(y)$ are uniquely determined from (2.20).

The fact that the solution to (2.17), which satisfies (2.16), equals to the solution to (2.15) – (2.16) follows from the uniqueness of the solution to (2.15) – (2.16) and (2.17) – (2.16), and from the observation that the solution to (2.15) – (2.16) solves (2.17) – (2.16). The uniqueness of the solution to (2.17) – (2.16) is a well-known result.

Let us prove uniqueness of the solution to (2.15) – (2.16). If there were two solutions, G_1 and G_2 , to (2.15) – (2.16), then their difference $G := G_1 - G_2$, would solve the problem:

$$PG = 0 \text{ in } \mathbb{R}, \quad G = 0 \text{ for } x < y. \quad (2.21)$$

By the uniqueness of the solution to the Cauchy problem, it follows that $G \equiv 0$. Note that this conclusion holds in the space of distributions as well, because equation (2.21) has only the classical solutions, as follows from the ellipticity of P . Thus the claim is proved. $\square$

From (2.8) and (2.14) – (2.16) one gets:

$$\begin{aligned} h &= \int_0^x G(x, y) Qf \, dy + \int_0^x G(x, y) \sum_{j=0}^{n-\alpha-1} [a_j^- \delta^{(j)}(y) + a_j^+ \delta^{(j)}(y-L)] \, dy \\ &= \int_0^x G(x, y) Qf \, dy + \sum_{j=0}^{n-\alpha-1} (-1)^j \left[G_y^{(j)}(x, y) \Big|_{y=0} a_j^- + G_y^{(j)}(x, y) \Big|_{y=L} a_j^+ \right] \\ &:= \int_0^x G(x, y) Qf \, dy + H(x). \end{aligned} \quad (2.22)$$

It follows from (2.22) that $h \in H^{-\alpha}(\mathbb{R})$ and

$$h = 0 \text{ for } x < 0, \quad (2.23)$$

that is, $(h, \varphi) = 0 \, \forall \varphi \in C_0^\infty(\mathbb{R})$ such that $\text{supp } \varphi \subset (-\infty, 0)$. In order to guarantee that $h \in \dot{H}^{-\alpha}(0, L)$ one has to satisfy the condition

$$h = 0 \text{ for } x > L. \quad (2.24)$$

Conditions (2.23) and (2.24) together are equivalent to $\text{supp } h \subset [0, L]$. Note that although $Qf \in \dot{H}^{-\frac{n+m}{2}}(0, L)$, so that Qf is a distribution, the integral $\int_0^x G(x, y) Qf \, dy = \int_{-\infty}^\infty G(x, y) Qf \, dy$ is well defined as the unique solution to the problem $Pw = Qf$, $w = 0$ for $x < 0$.

Let us prove that conditions (2.23) and (2.24) determine the constants $a_j^\pm$, $0 \leq j \leq \frac{n+m}{2} - 1$, uniquely.

If this is proved, then Theorem 1.3 is proved, and formula (2.22) gives an analytical solution to equation (1.4) in $\dot{H}^{-\alpha}(0, L)$ provided that an algorithm for finding $a_j^\pm$ is given. Indeed, an algorithm for finding $G(x, y)$ consists of solving (2.16) – (2.17). Solving (2.16) – (2.17) is accomplished analytically by solving the linear algebraic system (2.20) and then using formula (2.18). We assume that m linearly independent solutions $\varphi_j(x)$ to (2.19) are known.

Let us derive an algorithm for calculation of the constants $a_j^\pm$, $0 \leq j \leq \frac{n+m}{2} - 1$, from conditions (2.23) – (2.24).

Because of (2.16), condition (2.23) is satisfied automatically by h defined in (2.22).

To satisfy (2.24) it is necessary and sufficient to have

$$\int_0^L G(x, y) Q f dy + H(x) \equiv 0 \text{ for } x > L. \quad (2.25)$$

By (2.18), and because the system $\{\varphi_j\}_{1 \leq j \leq m}$ is linearly independent, equation (2.25) is equivalent to the following set of equations:

$$\int_0^L c_k(y) Q f dy + \sum_{j=0}^{\frac{n+m}{2}-1} (-1)^j \left[c_k^{(j)}(0) a_j^- + c_k^{(j)}(L) a_j^+ \right] = 0, \quad 1 \leq k \leq m. \quad (2.26)$$

Let us check that there are exactly m independent constants $a_j^\pm$ and that all the constants $a_j^\pm$ are uniquely determined by linear system (2.26).

If there are m independent constants $a_j^\pm$ and other constants can be linearly represented through these, then linear algebraic system (2.26) is uniquely solvable for these constants provided that the corresponding homogeneous system has only the trivial solution. If $f = 0$, then $h = 0$, as follows from Theorem 1.1, and $g = 0$ in (2.14). Therefore $a_j^\pm = 0 \forall j$, and system (2.26) determines the constants $a_j^\pm \forall j$ uniquely.

Finally, let us prove that there are exactly m independent constants $a_j^\pm$. Indeed, in formula (2.8) there are $\frac{n}{2}$ linearly independent solutions $u_j^- \in L^2(-\infty, 0)$, so

$$u_- = \sum_{j=1}^{\frac{n}{2}} b_j^- u_j^-, \quad (2.27)$$

and, similarly, u_+ in (2.8) is of the form

$$u_+ = \sum_{j=1}^{\frac{n}{2}} b_j^+ u_j^+, \quad (2.28)$$

where $u_j^+ \in L^2(0, \infty)$. Condition $F \in H^\alpha(\mathbb{R})$ implies

$$\sum_{j=1}^{\frac{n}{2}} b_j^- (u_j^-)^{(k)} = f^{(k)} \text{ at } x = 0, \quad 0 \leq k \leq \alpha - 1 = \frac{n-m}{2} - 1, \quad (2.29)$$

and

$$\sum_{j=1}^{\frac{n}{2}} b_j^+(u_j^+)^{(k)} = f^{(k)} \text{ at } x = L, \quad 0 \leq k \leq \frac{n-m}{2} - 1. \quad (2.30)$$

Equations (2.29) and (2.30) imply that there are $\frac{n}{2} - \frac{n-m}{2} = \frac{m}{2}$ independent constants b_j^- and $\frac{m}{2}$ independent constants b_j^+ , and the remaining $n-m$ constants b_j^- and b_j^+ can be represented through these m constants by solving linear systems (2.29) and (2.30) with respect to, say, first $\frac{n-m}{2}$ constants, for example, for system (2.29), for the constants b_j^- , $1 \leq j \leq \frac{n-m}{2}$. This can be done uniquely because the matrices of the linear systems (2.29) and (2.30) are nonsingular: they are Wronskians of linearly independent solutions $\{u_j^-\}_{1 \leq j \leq \frac{n-m}{2}}$ and $\{u_j^+\}_{1 \leq j \leq \frac{n-m}{2}}$.

The constants $a_j^\pm$ can be expressed in terms of $b_j^\pm$ and f by linear relations. Thus, there are exactly m independent constants $a_j^\pm$. This completes the proof of Theorem 1.3. $\square$

Remark 2.1. In [2, pp. 317-337] a theory of singular perturbations for the equations of the form

$$\varepsilon h_\varepsilon + R h_\varepsilon = f \quad (2.31)$$

is developed for a class of integral operators with a convolution kernels $R(x, y) = R(x-y)$. This theory can be generalized to the class of kernels $R(x, y)$ studied in the present paper. The basic interesting problem is: for any $\varepsilon > 0$ equation (2.31) has a unique solution $h_\varepsilon \in L^2(0, L)$; how can one find the asymptotic behavior of h_ε as $\varepsilon \rightarrow 0$? The limit h of h_ε as $\varepsilon \rightarrow 0$ should solve equation $Rh = f$ and, in general, h is a distribution, $h \in \dot{H}^{-\alpha}(0, L)$. The theory presented in [2, pp. 317-337] allows one to solve the above problem for the class of kernels studied in the present paper.

Remark 2.2. Theorems 1.1 and 1.2 and their proofs remain valid in the case when equation (1.4) is replaced by the

$$Rh := \int_D R(x, y) h(y) dy = f, \quad x \in \overline{D}. \quad (2.32)$$

Here $D \subset \mathbb{R}^r$, $r > 1$, is a bounded domain with a smooth boundary S , $\overline{D}$ is the closure of D , $R(x, y)$ solves (1.7), where P and Q are uniformly elliptic differential operators with smooth coefficients, $\text{ord} P = m \geq 0$, $\text{ord} Q = n > m$, equation $Qh = 0$ has only the trivial solution in $H^\beta(\mathbb{R}^r)$ for any fixed real number β . Under the above assumptions, one can prove that the operator defined by the kernel $R(x, y)$ is a pseudodifferential elliptic operator of order -2α , where $\alpha := \frac{n-m}{2}$. We do not assume that P and/or Q are selfadjoint or that P and Q commute. Therefore Theorems 1.1 and 1.2 for equation (2.32) generalize the results from [1]. An analog of Remark 2.1 holds for the multidimensional equation (2.31) as well. Equation (2.32) is the basic integral equation of random fields estimation theory [1].

In the short announcement by L.Piterbarg, Differentsialnye Uravneniya, 17, (1981), 2278-2279, (in Russian), some results concerning equation (2.32) are announced, but the author is not aware of the published proofs of these results.
